# 1 Introduction

This document contains a comprehensive collection of algorithms, data structures, and templates for competitive programming. Each section includes implementation details, time complexity analysis, and usage examples.

## 1.1 How to Use This Reference

- **Code Templates:** Ready-to-use implementations
- **Complexity Analysis:** Time and space complexity for each algorithm
- **Usage Examples:** Practical examples and edge cases
- **Notes:** Important implementation details and optimizations

## 2 Data Structures

### 2.1 STL Basics

This section covers the essential C++ Standard Template Library (STL) data structures commonly used in competitive programming.

#### 2.1.1 Important STL Concepts

- **Containers:** Data structures that hold objects (vector, set, map, etc.)
- **Iterators:** Objects that point to elements in containers
- **Algorithms:** Functions that operate on containers (sort, find, etc.)
- **Function Objects:** Objects that can be called like functions
- **Allocators:** Manage memory allocation for containers

#### 2.1.2 Common STL Operations

- **Insertion:** `insert()`, `push_back()`, `emplace()`
- **Deletion:** `erase()`, `pop_back()`, `clear()`
- **Access:** `at()`, `operator[]`, `front()`, `back()`
- **Size:** `size()`, `empty()`, `capacity()`
- **Iteration:** Range-based for loops, iterators, `begin()`, `end()`

#### 2.1.3 Performance Considerations

- **Vector:**  $O(1)$  amortized insertion at end,  $O(n)$  insertion in middle
- **Set/Map:**  $O(\log n)$  for insert, delete, search (Red-Black tree)
- **Unordered Set/Map:**  $O(1)$  average case,  $O(n)$  worst case (hash table)
- **Stack/Queue:**  $O(1)$  for push/pop operations
- **Priority Queue:**  $O(\log n)$  for push/pop operations

#### 2.1.4 Memory Management

- **Vector:** Automatically grows, use `reserve()` to pre-allocate
- **Set/Map:** Memory allocated per node, efficient for sparse data
- **Unordered:** Memory allocated in buckets, good for dense data
- **Stack/Queue:** Memory allocated as needed, efficient for LIFO/FIFO

### 2.1.5 Vectors and Arrays

#### 1: Basic Vector Operations

```
1 // Vector initialization
2 vector<int> v; // Empty vector
3 vector<int> v(5); // Size 5, initialized with 0s
4 vector<int> v(5, 2); // Size 5, initialized with 2s
5 vector<int> v = {1, 2, 3}; // Direct initialization
6
7 // Basic operations
8 v.push_back(4); // Add element to end
9 v.pop_back(); // Remove last element
10 v.size(); // Get current size
11 v.empty(); // Check if empty
12 v.front(); // First element
13 v.back(); // Last element
14 v.clear(); // Remove all elements
15
16 // Access and iteration
17 for(int i = 0; i < v.size(); i++) {
18     cout << v[i] << " "; // Using index
19 }
20 for(int x : v) { // Range-based for loop
21     cout << x << " ";
22 }
```

#### 2: 2D Vector Operations

```
1 // 2D vector initialization
2 vector<vector<int>> grid(n, vector<int>(m)); // n x m grid
3 vector<vector<int>> grid = { // Direct init
4     {1, 2, 3},
5     {4, 5, 6},
6     {7, 8, 9}
7 };
8
9 // Access elements
10 grid[i][j] = value; // Set value
11 int value = grid[i][j]; // Get value
12
13 // Common operations
14 for(int i = 0; i < grid.size(); i++) {
15     for(int j = 0; j < grid[i].size(); j++) {
16         cout << grid[i][j] << " ";
17     }
18     cout << "\n";
19 }
```

### 2.1.6 Sets and Maps

#### 3: Set and Unordered Set

```
1 // Set (ordered)
2 set<int> s; // Ordered unique elements
3 s.insert(5); // O(log n) insertion
4 s.erase(5); // O(log n) deletion
5 auto it = s.find(5); // O(log n) search
6 auto it = s.lower_bound(5); // First element >= 5
7 auto it = s.upper_bound(5); // First element > 5
8
9 // Unordered Set (hash table)
10 unordered_set<int> us; // Unordered unique elements
11 us.insert(5); // O(1) average case
12 us.erase(5); // O(1) average case
13 auto it = us.find(5); // O(1) average case
```

#### 4: Map and Unordered Map

```
1 // Map (ordered)
2 map<string, int> m; // Key-value pairs
3 m["apple"] = 5; // O(log n) insertion
4 m.erase("apple"); // O(log n) deletion
5 auto it = m.find("apple"); // O(log n) search
6
7 // Unordered Map (hash table)
8 unordered_map<string, int> um; // Hash table
9 um["apple"] = 5; // O(1) average case
10 um.erase("apple"); // O(1) average case
11 auto it = um.find("apple"); // O(1) average case
```

#### 5: Multiset and Multimaps Operations

```
1 // Multiset (allows duplicates)
2 multiset<int> ms;
3 ms.insert(5); // Can insert multiple 5s
4 ms.erase(5); // Erases all 5s
5 ms.erase(ms.find(5)); // Erases one occurrence
6
7 // Multimaps (multiple values per key)
8 multimap<string, int> mm;
9 mm.insert({"key", 1});
10 mm.insert({"key", 2}); // Same key, different value
11 auto range = mm.equal_range("key"); // Get all values
```

### 2.1.7 Priority Queue and Heaps

Priority queues in C++ use comparators with reversed logic. By default, `priority_queue<int>` creates a max-heap.

#### 6: Basic Priority Queue

```
1 // Max heap (default)
2 priority_queue<int> maxHeap;
3 // Min heap using greater<int>
4 priority_queue<int, vector<int>, greater<int>> minHeap;
5 // Custom comparator for complex types
6 struct Compare {
7     bool operator()(const Point& a, const Point& b) {
8         // Note: reversed logic compared to set/map
9         if (a.x != b.x) return a.x > b.x;
10        return a.y > b.y;
11    }
12 };
13 priority_queue<Point, vector<Point>, Compare> pq;
```

### 2.1.8 Stack and Queue

#### 7: Stack and Queue Operations

```
1 // Stack (LIFO)
2 stack<int> s;
3 s.push(5);           // Add element
4 s.pop();             // Remove top element
5 s.top();             // Access top element
6 s.empty();           // Check if empty
7 s.size();            // Get size
8 // Queue (FIFO)
9 queue<int> q;
10 q.push(5);           // Add element
11 q.pop();             // Remove front element
12 q.front();           // Access front element
13 q.back();            // Access back element
14 q.empty();           // Check if empty
15 q.size();            // Get size
16 // Deque (double-ended queue)
17 deque<int> dq;
18 dq.push_front(5);    // Add to front
19 dq.push_back(5);     // Add to back
20 dq.pop_front();      // Remove from front
21 dq.pop_back();       // Remove from back
22 dq.front();          // Access front
23 dq.back();           // Access back
```

### 2.1.9 Bitset

Bitset provides space-efficient storage for boolean values.

#### 8: Bitset Operations

```
1 // Bitset initialization
2 bitset<32> bs;           // 32-bit bitset
3 bitset<32> bs("1010");   // From binary string
4 bitset<32> bs(42);        // From integer
5
6 // Basic operations
7 bs.set(5);               // Set bit at position 5
8 bs.reset(5);             // Reset bit at position 5
9 bs.flip(5);              // Flip bit at position 5
10 bs.test(5);              // Check if bit is set
11 bs.count();              // Count set bits
12 bs.size();               // Total number of bits
13
14 // Bitwise operations
15 bitset<32> a("1010"), b("1100");
16 auto c = a & b;          // AND
17 auto d = a | b;          // OR
18 auto e = a ^ b;          // XOR
19 auto f = ~a;             // NOT
20
21 // Useful for competitive programming
22 bs.set();                 // Set all bits
23 bs.reset();               // Reset all bits
24 bs.flip();                // Flip all bits
```

### 2.1.10 Bit Manipulation

Advanced bit manipulation techniques and tricks for competitive programming.

#### 9: Basic Bit Operations

```
1 bool getBit(long long n, int i) { return (n >> i) & 1; }
2 long long setBit(long long n, int i) { return n | (1LL << i); }
3 long long clearBit(long long n, int i) { return n & ~(1LL << i); }
4 long long flipBit(long long n, int i) { return n ^ (1LL << i); }
5 long long updateBit(long long n, int i, bool val) {
6     return val ? setBit(n, i) : clearBit(n, i);
7 }
```

#### 10: Bit Tricks

```
1 long long rightmostBit(long long n) { return n & -n; }
2 long long turnOffRightmost(long long n) { return n & (n - 1); }
3 long long turnOnRightmost(long long n) { return n | (n + 1); }
4 bool isPowerOfTwo(long long n) { return n > 0 && (n & (n - 1)) == 0; }
5 long long fastMod(long long n, long long mod) { return n & (mod - 1); }
6 int popcount(long long n) { return __builtin_popcountll(n); }
7 int leadingZeros(long long n) { return __builtin_clzll(n); }
8 int trailingZeros(long long n) { return __builtin_ctzll(n); }
9 int log2Floor(long long n) { return 63 - __builtin_clzll(n); }
```

#### 11: Bitmask Patterns

```
1 long long createMask(int n) { return (1LL << n) - 1; }
2 long long extractBits(long long n, int i, int j) {
3     return (n >> i) & createMask(j - i + 1);
4 }
5 long long setRange(long long n, int i, int j) {
6     return n | (createMask(j - i + 1) << i);
7 }
8 long long clearRange(long long n, int i, int j) {
9     return n & ~(createMask(j - i + 1) << i);
10 }
11 long long swapBits(long long n, int i, int j) {
12     if (getBit(n, i) != getBit(n, j)) n = flipBit(flipBit(n, i), j);
13     return n;
14 }
15 long long reverseBits(long long n, int bits = 64) {
16     long long result = 0;
17     for (int i = 0; i < bits; i++)
18         if (getBit(n, i)) result = setBit(result, bits - 1 - i);
19     return result;
20 }
```

## 12: Subset Generation

```

1 // Generate all subsets:
2 // for(int mask = 0; mask < (1 << n); mask++)
3 // Generate all submasks:
4 // for(int sub = mask; ; sub = (sub - 1) & mask) { if(!sub) break; }
5 // Generate k-bit subsets:
6 // if(__builtin_popcount(mask) == k)
7
8 long long nextPermutation(long long n) {
9     long long c = n, c0 = 0, c1 = 0;
10    while (((c & 1) == 0) && c != 0) { c0++; c >>= 1; }
11    while ((c & 1) == 1) { c1++; c >>= 1; }
12    if (c0 + c1 >= 31) return -1;
13
14    long long pos = c0 + c1;
15    n = setBit(n, pos);
16    n = clearBit(n, pos - 1);
17    n = n & (~((1LL << (pos - 1)) - 1));
18    n = n | ((1LL << (c1 - 1)) - 1);
19    return n;
20 }

```

## 13: XOR Range

```

1 long long xorRange(long long n) {
2     int mod = n % 4;
3     return mod == 1 ? 1 : mod == 2 ? n + 1 : mod == 3 ? 0 : n;
4 }
5
6 long long xorRange(long long l, long long r) {
7     return xorRange(r) ^ xorRange(l - 1);
8 }

```

## 14: Find Two Unique Numbers

```

1 pair<int, int> findTwoUnique(vector<int>& arr) {
2     int xorAll = 0;
3     for (int x : arr) xorAll ^= x;
4     int rightmost = xorAll & -xorAll;
5     int x = 0, y = 0;
6     for (int num : arr) {
7         if (num & rightmost) x ^= num;
8         else y ^= num;
9     }
10    return {x, y};
11 }

```

## 15: Max XOR Subset

```

1 int maxXorSubset(vector<int> arr) {
2     for (int bit = 30; bit >= 0; bit--) {
3         int pivot = -1;
4         for (int i = 0; i < arr.size(); i++) {
5             if (getBit(arr[i], bit)) { pivot = i; break; }
6         }
7         if (pivot == -1) continue;
8
9         swap(arr[0], arr[pivot]);
10        for (int i = 1; i < arr.size(); i++) {
11            if (getBit(arr[i], bit)) arr[i] ^= arr[0];
12        }
13        arr.erase(arr.begin());
14    }
15    int result = 0;
16    for (int x : arr) result ^= x;
17    return result;
18 }

```

## 16: Bitmask DP Helpers

```

1
2 bool hasAdjacent(int mask, int n) {
3     return (mask & (mask << 1)) || (getBit(mask, 0) && getBit(mask, n - 1))
4     ;
5 }
6
7 int addIfValid(int mask, int pos, int n) {
8     if ((pos > 0 && getBit(mask, pos - 1)) ||
9         (pos < n - 1 && getBit(mask, pos + 1)) ||
10        (pos == 0 && n > 1 && getBit(mask, n - 1)) ||
11        (pos == n - 1 && n > 1 && getBit(mask, 0)))
12        return -1;
13    return setBit(mask, pos);
14 }
15
16 // Additional useful one-liners:
17 // Check if all bits in range [i,j] are set: ((n >> i) & createMask(j-i+1))
18 // == createMask(j-i+1)
19 // Toggle all bits: n ^ createMask(totalBits)
20 // Isolate rightmost n bits: n & createMask(n)
21 // Check if n has exactly k bits set: __builtin_popcount(n) == k
22 // Get position of rightmost set bit: __builtin_ctz(n)
23 // Get position of leftmost set bit: 31 - __builtin_clz(n) (for 32-bit)
24 // Set all bits from position i to end: n | (~0 << i)
25 // Clear all bits from position i to end: n & ((1 << i) - 1)

```

### 2.1.11 Ordered Set Template

C++ ordered sets using Policy-Based Data Structures (PBDS) for advanced operations.

#### 17: Ordered Set Template

```

1 #include <ext/pb_ds/assoc_container.hpp>
2 #include <ext/pb_ds/tree_policy.hpp>
3 using namespace __gnu_pbds;
4 // Ordered set (unique elements, ascending)
5 template<class T> using ordered_set = tree<T, null_type, less<T>,
    rb_tree_tag, tree_order_statistics_node_update>;
6
7 // Ordered multiset (allows duplicates, ascending)
8 template<class T> using ordered_multiset = tree<T, null_type, less_equal<T>,
    rb_tree_tag, tree_order_statistics_node_update>;
9
10 // Ordered set (unique elements, descending)
11 template<class T> using ordered_set_desc = tree<T, null_type, greater<T>,
    rb_tree_tag, tree_order_statistics_node_update>;
12
13 // Ordered multiset (allows duplicates, descending)
14 template<class T> using ordered_multiset_desc = tree<T, null_type,
    greater_equal<T>, rb_tree_tag, tree_order_statistics_node_update>;

```

#### 18: Ordered Set Functions

```

1 // order_of_key(k): #elements < k; find_by_order(k): kth element (0-indexed)
2 // insert(), erase(), find() as in set
3 ordered_multiset<int> ss; ss.insert(5); ss.insert(2); ss.insert(7); ss.
    insert(2);
4 cout << ss.order_of_key(5) << endl; // 3
5 cout << *ss.find_by_order(1) << endl; // 2
6 ss.erase(ss.find_by_order(ss.order_of_key(2))); // erase one '2'

```

#### 19: Custom Comparator for Ordered Set

```

1 template<class T>
2 struct custom_compare {
3     bool operator()(const T& a, const T& b) const {
4         if (a == b) return true; // Keep duplicates
5         return a > b; // Sort descending
6     }
7 };
8 template<class T> using ordered_multiset_custom = tree<T, null_type,
    custom_compare<T>, rb_tree_tag, tree_order_statistics_node_update>;

```

## 2.2 Advanced Data Structures

### 2.2.1 Segment Tree (Iterative)

Efficient range query data structure supporting point updates and range queries.

20: Segment Tree for Range Sum

```

1 struct SegmentTree {
2     int n;
3     vector<int> tree;
4
5     SegmentTree(const vector<int>& v) {
6         n = v.size();
7         tree.resize(n << 1);
8         for (int i = 0; i < n; i++)
9             tree[i + n] = v[i];
10        for (int i = n - 1; i > 0; i--)
11            tree[i] = tree[i << 1] + tree[i << 1 | 1];
12    }
13
14    void update(int pos, int value) {
15        tree[pos += n] = value;
16        for (pos >>= 1; pos > 0; pos >>= 1)
17            tree[pos] = tree[pos << 1] + tree[pos << 1 | 1];
18    }
19
20    int query(int l, int r) { // inclusive range [l, r]
21        int res = 0;
22        for (l += n, r += n + 1; l < r; l >>= 1, r >>= 1) {
23            if (l & 1) res += tree[l++];
24            if (r & 1) res += tree[--r];
25        }
26        return res;
27    }
28 };

```

21: Segment Tree Example Usage

```

1 int main() {
2     vector<int> a = {2, 1, 5, 3, 4};
3     SegmentTree st(a);
4
5     cout << st.query(1, 3) << "\n"; // 1 + 5 + 3 = 9
6     st.update(2, 0);                // a[2] = 0
7     cout << st.query(1, 3) << "\n"; // 1 + 0 + 3 = 4
8 }

```

## 22: Segment Tree for Range Maximum

```

1 struct SegmentTree {
2     int n;
3     vector<int> tree;
4
5     SegmentTree(const vector<int>& v) {
6         n = v.size();
7         tree.resize(n << 1);
8         for (int i = 0; i < n; i++)
9             tree[i + n] = v[i];
10        for (int i = n - 1; i > 0; i--)
11            tree[i] = max(tree[i << 1], tree[i << 1 | 1]);
12    }
13
14    void update(int pos, int value) {
15        tree[pos += n] = value;
16        for (pos >>= 1; pos > 0; pos >>= 1)
17            tree[pos] = max(tree[pos << 1], tree[pos << 1 | 1]);
18    }
19
20    int query(int l, int r) { // inclusive range [l, r]
21        int res = INT_MIN;
22        for (l += n, r += n + 1; l < r; l >>= 1, r >>= 1) {
23            if (l & 1) res = max(res, tree[l++]);
24            if (r & 1) res = max(res, tree[--r]);
25        }
26        return res;
27    }
28 };

```

## 23: Segment Tree Max Example Usage

```

1 int main() {
2     vector<int> a = {2, 1, 5, 3, 4};
3     SegmentTree st(a);
4
5     cout << st.query(1, 3) << "\n"; // max(1, 5, 3) = 5
6     st.update(2, 0);                // a[2] = 0
7     cout << st.query(1, 3) << "\n"; // max(1, 0, 3) = 3
8 }

```

### 2.2.2 Disjoint Set Union (DSU)

Optimized union-find data structure with path compression and union by size.

24: DSU with Vector

```
1 struct DSU {
2     vector<int> parent, size;
3
4     DSU(int n) {
5         parent.resize(n);
6         size.resize(n);
7         for (int i = 0; i < n; i++) {
8             parent[i] = i;
9             size[i] = 1;
10        }
11    }
12
13    int findParent(int x) {
14        if (parent[x] == x) return x;
15        return parent[x] = findParent(parent[x]);
16    }
17
18    bool sameGroup(int x, int y) {
19        return findParent(x) == findParent(y);
20    }
21
22    void merge(int x, int y) {
23        int rootX = findParent(x);
24        int rootY = findParent(y);
25        if (rootX == rootY) return;
26        if (size[rootX] < size[rootY]) swap(rootX, rootY);
27        parent[rootY] = rootX;
28        size[rootX] += size[rootY];
29    }
30 };
```

25: DSU Example Usage

```
1 int main() {
2     DSU dsu(10);
3
4     dsu.merge(1, 2);
5     dsu.merge(2, 3);
6     dsu.merge(4, 5);
7
8     cout << (dsu.sameGroup(1, 3)) << "\n"; // 1 (true)
9     cout << (dsu.sameGroup(1, 5)) << "\n"; // 0 (false)
10 }
```

## 26: DSU with Unordered Map

```
1 struct DSUMap {
2     unordered_map<int, int> parent, size;
3
4     void makeSet(int x) {
5         if (!parent.count(x)) {
6             parent[x] = x;
7             size[x] = 1;
8         }
9     }
10
11     int findParent(int x) {
12         makeSet(x);
13         if (parent[x] == x) return x;
14         return parent[x] = findParent(parent[x]);
15     }
16
17     bool sameGroup(int x, int y) {
18         return findParent(x) == findParent(y);
19     }
20
21     void merge(int x, int y) {
22         int rootX = findParent(x);
23         int rootY = findParent(y);
24         if (rootX == rootY) return;
25         if (size[rootX] < size[rootY]) swap(rootX, rootY);
26         parent[rootY] = rootX;
27         size[rootX] += size[rootY];
28     }
29 };
```

## 27: DSU Map Example Usage

```
1 int main() {
2     DSUMap dsu;
3     dsu.merge(100, 200);
4     dsu.merge(200, 300);
5     dsu.merge(400, 500);
6
7     cout << dsu.sameGroup(100, 300) << "\n"; // 1 (true)
8     cout << dsu.sameGroup(100, 500) << "\n"; // 0 (false)
9 }
```

## 3 Graph Algorithms

### 3.1 Depth-First Search (DFS)

Depth-First Search is a graph traversal algorithm that explores as far as possible along each branch before backtracking.

28: DFS Implementation

```
1 vector<vector<int>> graph; // Adjacency list
2 vector<bool> visited;
3
4 void dfs(int node) {
5     visited[node] = true;
6     cout << node << " "; // Process node
7
8     for (int neighbor : graph[node]) {
9         if (!visited[neighbor]) {
10             dfs(neighbor);
11         }
12     }
13 }
14
15 // Initialize and run DFS
16 void runDFS(int start, int n) {
17     graph.resize(n);
18     visited.resize(n, false);
19     dfs(start);
20 }
```

#### DFS Notes

- **Time Complexity:**  $O(V + E)$  where  $V$  = vertices,  $E$  = edges
- **Space Complexity:**  $O(V)$  for recursion stack
- **Use Cases:** Exploring all possibilities, backtracking, connected components
- **Recursive Nature:** Uses recursion, can cause stack overflow for very deep graphs

## 29: DFS with Connected Components

```
1 vector<vector<int>> graph;
2 vector<bool> visited;
3
4 void dfs(int node) {
5     visited[node] = true;
6
7     for (int neighbor : graph[node]) {
8         if (!visited[neighbor]) {
9             dfs(neighbor);
10        }
11    }
12 }
13
14 int countComponents(int n) {
15     visited.resize(n, false);
16     int components = 0;
17
18     for (int i = 0; i < n; i++) {
19         if (!visited[i]) {
20             dfs(i);
21             components++;
22         }
23     }
24     return components;
25 }
```

**Connected Components Notes**

- **Application:** Finding number of disconnected subgraphs
- **Algorithm:** Run DFS from each unvisited node
- **Result:** Each DFS call discovers one connected component
- **Complexity:** Still  $O(V + E)$  as each node/edge visited once

## 3.2 Breadth-First Search (BFS)

Breadth-First Search explores all vertices at the present depth before moving to vertices at the next depth level.

### 30: BFS Implementation

```
1 vector<vector<int>> graph; // Adjacency list
2 vector<bool> visited;
3
4 void bfs(int start) {
5     queue<int> q;
6     q.push(start);
7     visited[start] = true;
8
9     while (!q.empty()) {
10         int node = q.front();
11         q.pop();
12         cout << node << " "; // Process node
13
14         for (int neighbor : graph[node]) {
15             if (!visited[neighbor]) {
16                 visited[neighbor] = true;
17                 q.push(neighbor);
18             }
19         }
20     }
21 }
22
23 // Initialize and run BFS
24 void runBFS(int start, int n) {
25     graph.resize(n);
26     visited.resize(n, false);
27     bfs(start);
28 }
```

### BFS Notes

- **Time Complexity:**  $O(V + E)$  where  $V$  = vertices,  $E$  = edges
- **Space Complexity:**  $O(V)$  for queue
- **Use Cases:** Shortest path in unweighted graphs, level-order traversal
- **Queue-based:** Uses queue, explores level by level

## 31: BFS with Distance Calculation

```
1 vector<vector<int>> graph;  
2 vector<int> distance;  
3  
4 void bfsWithDistance(int start, int n) {  
5     queue<int> q;  
6     distance.resize(n, -1);  
7  
8     q.push(start);  
9     distance[start] = 0;  
10  
11     while (!q.empty()) {  
12         int node = q.front();  
13         q.pop();  
14  
15         for (int neighbor : graph[node]) {  
16             if (distance[neighbor] == -1) {  
17                 distance[neighbor] = distance[node] + 1;  
18                 q.push(neighbor);  
19             }  
20         }  
21     }  
22 }
```

## Distance BFS Notes

- **Shortest Path:** Guarantees shortest path in unweighted graphs
- **Distance Array:** Stores minimum distance from start to each node
- **Level Order:** Nodes at same distance processed together
- **Application:** Network routing, social network analysis

### 3.3 Dijkstra's Algorithm

Dijkstra's algorithm finds the shortest path from a source vertex to all other vertices in a weighted graph.

32: Dijkstra's Algorithm

```
1 vector<vector<pair<int, int>>> graph; // {neighbor, weight}
2 vector<int> distance;
3
4 void dijkstra(int start, int n) {
5     priority_queue<pair<int, int>, vector<pair<int, int>>, greater<pair<int,
6         int>>> pq;
7     distance.resize(n, INT_MAX);
8
9     distance[start] = 0;
10    pq.push({0, start});
11
12    while (!pq.empty()) {
13        int dist = pq.top().first;
14        int node = pq.top().second;
15        pq.pop();
16
17        if (dist > distance[node]) continue;
18
19        for (auto [neighbor, weight] : graph[node]) {
20            if (distance[node] + weight < distance[neighbor]) {
21                distance[neighbor] = distance[node] + weight;
22                pq.push({distance[neighbor], neighbor});
23            }
24        }
25    }
```

#### Dijkstra Notes

- **Time Complexity:**  $O((V + E) \log V)$  with priority queue
- **Space Complexity:**  $O(V)$  for distance array and priority queue
- **Requirement:** All edge weights must be non-negative
- **Greedy Algorithm:** Always picks the closest unvisited node

## 33: Dijkstra with Path Reconstruction

```

1 vector<vector<pair<int, int>>> graph;
2 vector<int> distance, parent;
3
4 void dijkstraWithPath(int start, int n) {
5     priority_queue<pair<int, int>, vector<pair<int, int>>, greater<pair<int,
6         int>>> pq;
7     distance.resize(n, INT_MAX);
8     parent.resize(n, -1);
9
10    distance[start] = 0;
11    pq.push({0, start});
12
13    while (!pq.empty()) {
14        int dist = pq.top().first;
15        int node = pq.top().second;
16        pq.pop();
17
18        if (dist > distance[node]) continue;
19
20        for (auto [neighbor, weight] : graph[node]) {
21            if (distance[node] + weight < distance[neighbor]) {
22                distance[neighbor] = distance[node] + weight;
23                parent[neighbor] = node;
24                pq.push({distance[neighbor], neighbor});
25            }
26        }
27    }
28
29    vector<int> getPath(int end) {
30        vector<int> path;
31        for (int node = end; node != -1; node = parent[node]) {
32            path.push_back(node);
33        }
34        reverse(path.begin(), path.end());
35        return path;
36    }

```

## Path Reconstruction Notes

- **Parent Array:** Stores predecessor of each node in shortest path
- **Path Recovery:** Backtrack from destination to source
- **Reverse Order:** Path is built backwards, then reversed
- **Application:** Navigation systems, network routing

### 3.4 Floyd-Warshall Algorithm

Floyd-Warshall finds shortest paths between all pairs of vertices in a weighted graph.

34: Floyd-Warshall Algorithm

```
1 int main() {
2     int INF = 1e9;
3     int n = 4;
4     vector<vector<int>> mat = {
5         {0, 3, INF, 7},
6         {8, 0, 2, INF},
7         {5, INF, 0, 1},
8         {2, INF, INF, 0}
9     };
10
11     for (int mid = 0; mid < n; mid++)
12         for (int from = 0; from < n; from++)
13             for (int to = 0; to < n; to++)
14                 mat[from][to] = min(mat[from][to], mat[from][mid] + mat[mid][to]);
15
16     for (int from = 0; from < n; from++) {
17         for (int to = 0; to < n; to++)
18             cout << (mat[from][to] == INF ? -1 : mat[from][to]) << " ";
19         cout << "\n";
20     }
21 }
```

#### Floyd-Warshall Notes

- **Time Complexity:**  $O(V^3)$  - cubic time complexity
- **Space Complexity:**  $O(V^2)$  for distance matrix
- **All Pairs:** Finds shortest path between every pair of vertices
- **Handles Negatives:** Can detect negative cycles

### 3.5 Topological Sort

Topological sort orders vertices in a directed acyclic graph (DAG) so that all edges point forward.

#### 35: Topological Sort with DFS

```
1 vector<vector<int>> graph;
2 vector<bool> visited;
3 vector<int> topoOrder;
4
5 void dfs(int node) {
6     visited[node] = true;
7
8     for (int neighbor : graph[node]) {
9         if (!visited[neighbor]) {
10             dfs(neighbor);
11         }
12     }
13
14     topoOrder.push_back(node);
15 }
16
17 vector<int> topologicalSort(int n) {
18     visited.resize(n, false);
19     topoOrder.clear();
20
21     for (int i = 0; i < n; i++) {
22         if (!visited[i]) {
23             dfs(i);
24         }
25     }
26
27     reverse(topoOrder.begin(), topoOrder.end());
28     return topoOrder;
29 }
```

#### DFS Topological Sort Notes

- **Post-order DFS:** Add node after visiting all neighbors
- **Reverse Result:** Final order is reversed DFS post-order
- **Requirement:** Graph must be a DAG (no cycles)
- **Application:** Build order, dependency resolution

## 36: Topological Sort with Kahn's Algorithm

```
1 vector<vector<int>> graph;
2 vector<int> inDegree;
3
4 vector<int> kahnTopologicalSort(int n) {
5     queue<int> q;
6     vector<int> result;
7
8     // Calculate in-degrees
9     inDegree.resize(n, 0);
10    for (int i = 0; i < n; i++) {
11        for (int neighbor : graph[i]) {
12            inDegree[neighbor]++;
13        }
14    }
15
16    // Add nodes with in-degree 0
17    for (int i = 0; i < n; i++) {
18        if (inDegree[i] == 0) {
19            q.push(i);
20        }
21    }
22
23    while (!q.empty()) {
24        int node = q.front();
25        q.pop();
26        result.push_back(node);
27
28        for (int neighbor : graph[node]) {
29            inDegree[neighbor]--;
30            if (inDegree[neighbor] == 0) {
31                q.push(neighbor);
32            }
33        }
34    }
35
36    return result;
37 }
```

## Kahn's Algorithm Notes

- **In-degree Tracking:** Count incoming edges for each node
- **Queue-based:** Process nodes with zero in-degree
- **Multiple Orders:** Can have multiple valid topological orders
- **Cycle Detection:** If result size < n, graph has cycle

### 3.6 Cycle Detection

Detecting cycles in directed and undirected graphs.

#### 37: Cycle Detection in Undirected Graph

```
1 vector<vector<int>> graph;
2 vector<bool> visited;
3
4 bool hasCycleUndirected(int node, int parent) {
5     visited[node] = true;
6
7     for (int neighbor : graph[node]) {
8         if (!visited[neighbor]) {
9             if (hasCycleUndirected(neighbor, node)) {
10                 return true;
11             }
12         } else if (neighbor != parent) {
13             return true;
14         }
15     }
16     return false;
17 }
18
19 bool detectCycleUndirected(int n) {
20     visited.resize(n, false);
21
22     for (int i = 0; i < n; i++) {
23         if (!visited[i]) {
24             if (hasCycleUndirected(i, -1)) {
25                 return true;
26             }
27         }
28     }
29     return false;
30 }
```

#### Undirected Cycle Detection Notes

- **Parent Tracking:** Avoid revisiting parent node
- **Back Edge:** Cycle if neighbor is visited but not parent
- **DFS-based:** Uses DFS to explore graph
- **Application:** Validating trees, network topology

## 38: Cycle Detection in Directed Graph

```
1 vector<vector<int>> graph;
2 vector<bool> visited, recStack;
3
4 bool hasCycleDirected(int node) {
5     visited[node] = true;
6     recStack[node] = true;
7
8     for (int neighbor : graph[node]) {
9         if (!visited[neighbor]) {
10             if (hasCycleDirected(neighbor)) {
11                 return true;
12             }
13         } else if (recStack[neighbor]) {
14             return true;
15         }
16     }
17
18     recStack[node] = false;
19     return false;
20 }
21
22 bool detectCycleDirected(int n) {
23     visited.resize(n, false);
24     recStack.resize(n, false);
25
26     for (int i = 0; i < n; i++) {
27         if (!visited[i]) {
28             if (hasCycleDirected(i)) {
29                 return true;
30             }
31         }
32     }
33     return false;
34 }
```

**Directed Cycle Detection Notes**

- **Recursion Stack:** Track nodes in current recursion path
- **Back Edge:** Cycle if neighbor is in recursion stack
- **Two Arrays:** visited for all nodes, recStack for current path
- **Application:** Deadlock detection, DAG validation

## 4 Dynamic Programming

### 4.1 Longest Increasing Subsequence (LIS)

The Longest Increasing Subsequence problem finds the longest subsequence of a given sequence such that all elements of the subsequence are sorted in increasing order.

#### 39: LIS - 2D DP Bottom-Up Implementation

```

1 int lengthOfLIS(vector<int>& nums) {
2     int n = nums.size();
3     vector<vector<int>> dp(n + 2, vector<int>(n + 2));
4
5     for (int i = n - 1; i >= 0; --i) {
6         for (int j = i - 1; j >= -1; --j) {
7             int curr = i + 1, prev = j + 1;
8             if (j == -1 || nums[i] > nums[j])
9                 dp[curr][prev] = dp[curr + 1][curr] + 1;
10            dp[curr][prev] = max(dp[curr][prev], dp[curr + 1][prev]);
11        }
12    }
13
14    // Reconstruct the LIS
15    vector<int> lis;
16    int i = 0, j = -1;
17    while (i < n) {
18        int curr = i + 1, prev = j + 1;
19        if (dp[curr][prev] == dp[curr + 1][curr] + 1 && (j == -1 || nums[i]
20            > nums[j])) {
21            lis.push_back(nums[i]);
22            j = i;
23        }
24        i++;
25    }
26    return dp[1][0];
27 }

```

#### LIS 2D DP Notes

- **Time Complexity:**  $O(n^2)$  - quadratic time
- **Space Complexity:**  $O(n^2)$  for 2D DP table
- **State Definition:**  $dp[i+1][j+1]$  represents LIS from index  $i$  with last element at  $j$
- **Reconstruction:** Can reconstruct the actual LIS sequence
- **Usage:** Use for understanding and simple cases

## 40: LIS - 1D DP Bottom-Up Implementation

```
1 int lengthOfLIS(vector<int>& nums) {
2     int n = nums.size();
3     vector<int> dp(n, 1);
4     for (int i = n - 1; i >= 0; --i)
5         for (int j = i + 1; j < n; ++j)
6             if (nums[j] > nums[i])
7                 dp[i] = max(dp[i], dp[j] + 1);
8
9     // Reconstruct the LIS
10    int maxLen = *max_element(dp.begin(), dp.end());
11    vector<int> lis;
12    for (int i = 0; i < n && maxLen; ++i)
13        if (dp[i] == maxLen) {
14            lis.push_back(nums[i]);
15            --maxLen;
16        }
17
18    return *max_element(dp.begin(), dp.end());
19 }
```

## LIS 1D DP Notes

- **Time Complexity:**  $O(n^2)$  with memoization
- **Space Complexity:**  $O(n)$  for 1D DP array
- **State Definition:**  $dp[i]$  is length of LIS ending at index  $i$
- **Base Case:**  $dp[i] = 1$  for all  $i$  (single element is valid LIS)
- **Advantage:** More space efficient than 2D approach

## 41: LIS - Recursive Implementation

```
1 int lengthOfLIS(const vector<int>& nums) {
2     int n = nums.size();
3     vector<vector<int>> dp(n + 1, vector<int>(n + 1, -1));
4
5     function<int(int, int)> calculateLIS = [&](int cur, int prev) {
6         if (cur == n) return 0;
7         int i = cur + 1, j = prev + 1;
8         int& res = dp[i][j];
9         if (res != -1) return res;
10
11         if (prev == -1 || nums[cur] > nums[prev])
12             res = max(res, 1 + calculateLIS(cur + 1, cur));
13
14         res = max(res, calculateLIS(cur + 1, prev));
15
16         return res;
17     };
18
19     return calculateLIS(0, -1);
20 }
```

## LIS Recursive Notes

- **Time Complexity:**  $O(n^2)$  with memoization
- **Space Complexity:**  $O(n^2)$  for DP table and recursion stack
- **Top-down DP:** Recursive approach with memoization
- **Base Case:** When  $cur == n$ , return 0
- **Memoization:** Stores results to avoid redundant calculations

## 42: LIS - Binary Search Implementation

```

1 int lengthOfLIS(const vector<int>& a) {
2     vector<int> lis;
3     for (int i = 0; i < a.size(); ++i) {
4         auto it = lower_bound(begin(lis), end(lis), a[i]);
5         it != end(lis) ? *it = a[i] : lis.push_back(a[i]);
6     }
7     return lis.size();
8 }
9
10 // Reconstruct the actual LIS sequence
11 vector<int> getLIS(const vector<int>& a) {
12     vector<int> lis, prev(a.size(), -1);
13     for (int i = 0; i < a.size(); ++i) {
14         auto it = lower_bound(begin(lis), end(lis), i, [&](int j, int k) {
15             return a[j] < a[k];
16         });
17         it != end(lis) ? *it = i : lis.push_back(i);
18         if (it != begin(lis)) prev[i] = *(it - 1);
19     }
20     vector<int> res;
21     for (int i = lis.back(); i != -1; i = prev[i]) {
22         res.push_back(a[i]);
23     }
24     reverse(begin(res), end(res));
25     return res;
26 }

```

## LIS Binary Search Notes

- **Time Complexity:**  $O(n \log n)$  - optimal approach
- **Space Complexity:**  $O(n)$  for LIS array and prev array
- **Binary Search:** Uses `lower_bound` for efficient insertion
- **Optimal Solution:** Best time complexity for LIS problem
- **Usage:** Use for optimal time complexity in practice
- **Reconstruction:** Can reconstruct the actual LIS sequence

## 43: LIS - Segment Tree Implementation

```

1 struct SegmentTree {
2     int n;
3     vector<int> tree;
4
5     SegmentTree(int _n) {
6         n = _n;
7         tree.resize(2 * _n);
8     }
9
10    void update(int pos, int value) {
11        tree[pos += n] = value;
12        for (pos >>= 1; pos > 0; pos >>= 1)
13            tree[pos] = max(tree[pos << 1], tree[pos << 1 | 1]);
14    }
15
16    int query(int l, int r) {
17        int res = 0;
18        for (l += n, r += n + 1; l < r; l >>= 1, r >>= 1) {
19            if (l & 1) res = max(res, tree[l++]);
20            if (r & 1) res = max(res, tree[--r]);
21        }
22        return res;
23    }
24 };
25
26 int lengthOfLIS(vector<int>& nums) {
27     SegmentTree seg(1e5 + 1);
28     int res = 0;
29     for (auto i : nums) {
30         i += 2e4; // Offset to handle negative numbers
31         int val = seg.query(0, i - 1) + 1; // Find max LIS ending before i
32         res = max(res, val);
33         seg.update(i, val); // Update the LIS at position i
34     }
35     return res;
36 }

```

## LIS Segment Tree Notes

- **Time Complexity:**  $O(n \log M)$  where  $M$  is the range of values
- **Space Complexity:**  $O(M)$  for segment tree
- **Advanced Approach:** Uses segment tree for range queries
- **Coordinate Compression:** Can handle large value ranges
- **Usage:** Use when you need range queries or advanced applications
- **Offset:**  $+2e4$  handles negative numbers

## 5 Backtracking

### 5.1 Subsets

Generate all possible subsets of a given array.

44: Subsets Implementation

```
1 #include <vector>
2 using namespace std;
3
4 vector<vector<int>> subsets(vector<int>& nums) {
5     vector<vector<int>> result;
6     vector<int> subset;
7
8     function<void(int)> generate = [&](int start) {
9         // Add the current subset to the result
10        result.push_back(subset);
11
12        // Try adding each remaining element to the current subset
13        for (int i = start; i < nums.size(); i++) {
14            subset.push_back(nums[i]);
15            generate(i + 1);
16            subset.pop_back();
17        }
18    };
19
20    generate(0);
21    return result;
22 }
```

#### Subsets Notes

- **Time Complexity:**  $O(2^n)$  where  $n$  is the number of elements
- **Space Complexity:**  $O(2^n)$  to store all subsets
- **Backtracking Pattern:** Choose  $\rightarrow$  Recurse  $\rightarrow$  Unchoose
- **Natural Generation:** Each recursive call decides whether to include each element
- **Empty Set:** Includes the empty set as a valid subset
- **No Duplicates:** Avoids duplicates by only considering elements from current index forward

## 5.2 Permutations

Generate all possible permutations of a given array.

### 45: Permutations Without Duplicates

```
1 #include <vector>
2 using namespace std;
3
4 vector<vector<int>> permuteUnique(vector<int>& nums) {
5     vector<vector<int>> result;
6     vector<int> comb;
7     vector<bool> visited(nums.size(), false);
8
9     function<void()> permute = [&]() {
10         if (comb.size() == nums.size()) {
11             result.push_back(comb);
12             return;
13         }
14         for (int i = 0; i < nums.size(); i++) {
15             if (visited[i]) continue;
16             visited[i] = true;
17             comb.push_back(nums[i]);
18             permute();
19             comb.pop_back();
20             visited[i] = false;
21         }
22     };
23
24     permute();
25     return result;
26 }
```

### Permutations Without Duplicates Notes

- **Time Complexity:**  $O(n!)$  where  $n$  is the number of elements
- **Space Complexity:**  $O(n!)$  to store all permutations
- **Visited Array:** Tracks which elements have been used
- **Perfect for Unique Elements:** Arrays with unique elements
- **All Orderings:** Generates all possible orderings of input array
- **Backtracking:** Uses visited array to prevent reusing elements

## 46: Permutations With Duplicates

```
1 #include <vector>
2 #include <unordered_map>
3 using namespace std;
4
5 vector<vector<int>> permuteWithDuplicates(vector<int>& nums) {
6     vector<vector<int>> result;
7     unordered_map<int, int> counter;
8     for (int num : nums) counter[num]++;
9
10    vector<int> comb;
11
12    function<void()> permute = [&]() {
13        if (comb.size() == nums.size()) {
14            result.push_back(comb);
15            return;
16        }
17        for (auto& item : counter) {
18            int num = item.first;
19            int count = item.second;
20            if (count == 0) continue;
21            comb.push_back(num);
22            counter[num]--;
23            permute();
24            comb.pop_back();
25            counter[num]++;
26        }
27    };
28
29    permute();
30    return result;
31 }
```

## Permutations With Duplicates Notes

- **Time Complexity:**  $O(n! \times n)$  due to factorial permutations and element checking
- **Space Complexity:**  $O(n!)$  to store the resulting permutations
- **Unordered Map:** Tracks frequency of each element
- **Prevents Duplicates:** More efficient for inputs with repeated elements
- **Counter Management:** Decrements and increments counter during backtracking
- **Usage:** Use when input array contains duplicate elements

### 5.3 Combinations

Generate all possible combinations of k elements from an array.

#### 47: Combinations Implementation

```
1 #include <vector>
2 using namespace std;
3
4 vector<vector<int>> combinations(vector<int>& nums, int k) {
5     vector<vector<int>> result;
6     vector<int> comb;
7
8     function<void(int)> combine = [&](int start) {
9         if (comb.size() == k) {
10             result.push_back(comb);
11             return;
12         }
13         for (int i = start; i < nums.size(); i++) {
14             comb.push_back(nums[i]);
15             combine(i + 1);
16             comb.pop_back();
17         }
18     };
19
20     combine(0);
21     return result;
22 }
```

#### Combinations Notes

- **Time Complexity:**  $O(C(n,k))$  or  $O(n!/(k!(n-k)!))$  where n is number of elements and k is size of each combination
- **Space Complexity:**  $O(C(n,k))$  to store all combinations
- **Starting Index:** Uses start parameter to avoid duplicates
- **Size Constraint:** Generates combinations of exactly size k
- **No Reuse:** No element is used more than once in each combination
- **Order Independent:** Unlike permutations, order doesn't matter in combinations

## 6 String Algorithms

### 6.1 C++ STL String Functions

Essential string manipulation functions from the C++ Standard Library.

48: STL String Functions

```
1 #include <string>
2 #include <algorithm>
3
4 string s = "Hello World";
5 // Basic operations
6 s.length();           // Get string length
7 s.size();             // Same as length()
8 s.empty();            // Check if empty
9 s.clear();            // Clear string
10 // Access elements
11 s[0];                // Access character
12 s.at(0);             // Bounds-checked access
13 s.front();           // First character
14 s.back();            // Last character
15 // String manipulation
16 s.substr(0, 5);       // Substring
17 s.find("World");      // Find substring
18 s.replace(0, 5, "Hi"); // Replace substring
19 s.insert(5, " ");      // Insert at position
20 // String algorithms
21 reverse(s.begin(), s.end()); // Reverse string
22 sort(s.begin(), s.end());    // Sort characters
23 transform(s.begin(), s.end(), s.begin(), ::tolower); // To lowercase
24 transform(s.begin(), s.end(), s.begin(), ::toupper); // To uppercase
25 // String concatenation
26 string s1 = "Hello";
27 string s2 = "World";
28 string result = s1 + " " + s2; // Concatenation
29 s1.append(s2);                 // Append to string
30 s1 += s2;                     // Append operator
```

#### STL String Notes

- **Time Complexity:** Most operations  $O(1)$  or  $O(n)$
- **Memory Efficient:** String uses dynamic allocation
- **STL Algorithms:** Can use all STL algorithms on strings
- **Character Access:** Direct indexing and bounds-checked access

## 6.2 Longest Substring Without Repeating Characters

Find the length of the longest substring without repeating characters.

49: Longest Substring Without Repeating Characters

```
1 int lengthOfLongestSubstring(string s) {  
2     vector<int> charIndex(128, -1); // ASCII characters  
3     int maxLength = 0;  
4     int start = 0;  
5  
6     for (int end = 0; end < s.length(); end++) {  
7         char currentChar = s[end];  
8  
9         // If character already seen, update start  
10        if (charIndex[currentChar] >= start) {  
11            start = charIndex[currentChar] + 1;  
12        }  
13  
14        charIndex[currentChar] = end;  
15        maxLength = max(maxLength, end - start + 1);  
16    }  
17  
18    return maxLength;  
19 }
```

### Longest Substring Notes

- **Sliding Window:** Uses two pointers technique
- **Time Complexity:**  $O(n)$  where  $n$  is string length
- **Space Complexity:**  $O(1)$  for fixed alphabet size
- **Character Tracking:** Uses array to track last position

### 6.3 Trie (Prefix Tree)

A trie is a tree-like data structure used to store a dynamic set of strings.

#### 50: Trie Node Implementation

```
1 struct TrieNode {  
2     vector<TrieNode*> children;  
3     bool isEndOfWord;  
4  
5     TrieNode() {  
6         children.resize(26, nullptr);  
7         isEndOfWord = false;  
8     }  
9 };
```

#### Trie Node Notes

- **Time Complexity:**  $O(1)$  for insertion and search
- **Space Complexity:**  $O(\text{ALPHABET\_SIZE} \times N \times M)$
- **Applications:** Prefix matching, autocomplete

## 51: Trie Implementation

```
1
2 class Trie {
3 private:
4     TrieNode* root;
5
6 public:
7     Trie() { root = new TrieNode(); }
8     void insert(string word) {
9         TrieNode* node = root;
10        for (char c : word) {
11            int index = c - 'a';
12            if (!node->children[index]) node->children[index] = new
13                TrieNode();
14            node = node->children[index];
15        }
16        node->isEndOfWord = true;
17    }
18    bool search(string word) {
19        TrieNode* node = root;
20        for (char c : word) {
21            int index = c - 'a';
22            if (!node->children[index]) return false;
23            node = node->children[index];
24        }
25        return node->isEndOfWord;
26    }
27    bool startsWith(string prefix) {
28        TrieNode* node = root;
29        for (char c : prefix) {
30            int index = c - 'a';
31            if (!node->children[index]) return false;
32            node = node->children[index];
33        }
34        return true;
35    }
36};
```

## Trie Notes

- **Time Complexity:**  $O(m)$  where  $m$  is string length
- **Space Complexity:**  $O(\text{ALPHABET\_SIZE} \times N \times M)$
- **Applications:** Prefix matching, autocomplete
- **Memory Usage:** Can be memory intensive for large datasets

## 7 Mathematics

### 7.1 Fast Power (Binary Exponentiation)

Efficiently compute large powers using binary exponentiation.

52: Binary Exponentiation - Iterative

```
1 int64_t power(int64_t base, int64_t exp) {  
2     int64_t result = 1;  
3     while (exp > 0) {  
4         if (exp & 1) result *= base;  
5         base *= base;  
6         exp >>= 1;  
7     }  
8     return result;  
9 }
```

53: Modular Exponentiation

```
1 int64_t modPower(int64_t base, int64_t exp, int64_t mod) {  
2     int64_t result = 1;  
3     base = base % mod;  
4     while (exp > 0) {  
5         if (exp & 1) result = (result * base) % mod;  
6         base = (base * base) % mod;  
7         exp >>= 1;  
8     }  
9     return result;  
10 }
```

#### Modular Exponentiation Notes

- **Time Complexity:**  $O(\log \text{exp})$  - logarithmic time
- **Space Complexity:**  $O(1)$  constant space
- **Modulo Arithmetic:** Handles large numbers with modulo
- **Overflow Prevention:** Essential for competitive programming
- **Applications:** Cryptography, number theory problems

## 7.2 GCD and LCM Functions

Greatest Common Divisor and Least Common Multiple functions.

### 54: GCD and LCM Functions

```
1 int gcd(int a, int b) {  
2     while (b != 0) {  
3         a %= b;  
4         swap(a, b);  
5     }  
6     return a;  
7 }  
8  
9 int lcm(int a, int b) {  
10     return (a / gcd(a, b)) * b;  
11 }
```

### GCD/LCM Notes

- **Time Complexity:**  $O(\log \min(a,b))$  for GCD
- **Space Complexity:**  $O(1)$  constant space
- **Euclidean Algorithm:** Efficient GCD calculation
- **LCM Formula:**  $\text{LCM}(a,b) = (a \times b) / \text{GCD}(a,b)$
- **Applications:** Number theory, fraction simplification

### 7.3 Combinatorics

Basic combinatorial functions with modular arithmetic support.

55: Standard nCr and nPr

```
1 // Don't use for n > 67 (int64_t overflow)
2 int64_t nCr(int n, int r) {
3     if (r < 0 || r > n) return 0;
4     if (r > n - r) r = n - r;
5     int64_t res = 1;
6     for (int i = 0; i < r; ++i) {
7         res *= (n - i);
8         res /= (i + 1);
9     }
10    return res;
11 }
12
13 // Don't use for n > 20 or large r (int64_t overflow)
14 int64_t nPr(int n, int r) {
15     if (r < 0 || r > n) return 0;
16     int64_t res = 1;
17     for (int i = 0; i < r; ++i)
18         res *= (n - i);
19     return res;
20 }
```

#### Standard Combinatorics Notes

- **Time Complexity:**  $O(r)$  for both nCr and nPr
- **Space Complexity:**  $O(1)$  constant space
- **Limits:**  $n \leq 67$  for nCr,  $n \leq 20$  for nPr
- **Optimization:** nCr uses symmetry  $C(n,r) = C(n,n-r)$
- **Applications:** Probability, counting problems

## 56: Combinatorics with Modular Arithmetic

```

1 #include <vector>
2 using namespace std;
3
4 class Combinatorics {
5 private:
6     static const int MOD = 1000000007;
7     vector<int64_t> f, inv;
8
9     int64_t pow(int64_t b, int64_t e) const {
10         int64_t r = 1;
11         while (e) {
12             if (e & 1) r = r * b % MOD;
13             b = b * b % MOD;
14             e >>= 1;
15         }
16         return r;
17     }
18
19 public:
20     Combinatorics(int n) : f(n + 1), inv(n + 1) {
21         f[0] = 1;
22         for (int i = 1; i <= n; ++i)
23             f[i] = f[i - 1] * i % MOD;
24         inv[n] = pow(f[n], MOD - 2);
25         for (int i = n - 1; i >= 0; --i)
26             inv[i] = inv[i + 1] * (i + 1) % MOD;
27     }
28     int64_t nCr(int n, int r) const {
29         if (r < 0 || r > n) return 0;
30         return f[n] * inv[r] % MOD * inv[n - r] % MOD;
31     }
32     int64_t nPr(int n, int r) const {
33         if (r < 0 || r > n) return 0;
34         return f[n] * inv[n - r] % MOD;
35     }
36 };

```

## Modular Combinatorics Notes

- **Preprocessing:**  $O(n)$  time and space for setup
- **Query Time:**  $O(1)$  per nCr/nPr call
- **Limits:**  $n$  up to  $10^6$  (uses 16MB for  $n=10^6$ )
- **Features:** Handles large  $n$ , fast for many queries
- **Fermat's Little Theorem:** Uses for modular inverse
- **Applications:** Large combinatorial problems

## 7.4 Sieve of Eratosthenes

Efficient algorithm to find all prime numbers up to a given limit.

57: Sieve of Eratosthenes

```

1 #include <bits/stdc++.h>
2 using namespace std;
3 // Time:  $O(n \log \log n)$ , Space:  $O(n)$ 
4 // Range: n up to  $10^7$  (typical CP limit)
5 // Memory: ~40MB for  $n=10^7$ 
6 class Sieve {
7 public:
8     vector<int> prime_factor, primes;
9
10    Sieve(int n) {
11        prime_factor.resize(n + 1);
12        for (int i = 0; i <= n; i++) prime_factor[i] = i;
13        for (int i = 2; i <= n; i++) {
14            if (prime_factor[i] == i) {
15                primes.push_back(i);
16                for (int j = i * i; j <= n; j += i)
17                    if (prime_factor[j] == j) prime_factor[j] = i;
18            }
19        }
20    }
21 };
22
23 int main() {
24     Sieve sieve(100);
25     for (int p : sieve.primes) cout << p << " ";
26     cout << "\n";
27     for (int i = 12; i <= 15; i++) {
28         cout << i << ": prime_factor=" << sieve.prime_factor[i] << "\n";
29     }
30     return 0;
31 }

```

### Sieve Notes

- **Time Complexity:**  $O(n \log \log n)$  - nearly linear
- **Space Complexity:**  $O(n)$  for boolean array
- **Prime Factors:** `sieve.prime_factor[x]` gives smallest prime factor
- **Prime List:** `sieve.primes` contains all primes up to  $n$
- **Memory Usage:** 40MB for  $n=10^7$
- **Applications:** Prime factorization, number theory

## 8 Notes & Utilities

### 8.1 Binary Conversions

Convert numbers between different bases.

#### 58: Binary to Decimal Conversion

```
1 // Convert binary string to decimal integer
2 string binaryStr = "1010";
3 int decimal = stoll(binaryStr, nullptr, 2);
4 // Result: 10
5
6 // Using bitset for larger binary strings
7 #include <bitset>
8 const int N = 32; // Enough for standard integers
9 int decimal = bitset<N>("1010").to_ulong();
10 // Result: 10
11
12 // For longer binary strings
13 const int LARGE_N = 10000; // For very large binary strings
14 unsigned long long largeDecimal = bitset<LARGE_N>(longBinaryStr).to_ullong()
    ;
```

#### 59: Decimal to Binary Conversion

```
1 #include <bitset>
2
3 // Convert decimal to binary string
4 int decimal = 10;
5 const int N = 8; // Number of bits to represent
6 string binaryStr = bitset<N>(decimal).to_string();
7 // Result: "00001010"
8
9 // Remove leading zeros if needed
10 binaryStr = binaryStr.substr(binaryStr.find('1') != string::npos ? binaryStr
    .find('1') : N-1);
11 // Result: "1010"
12
13 // Using std::format (C++20)
14 #include <format>
15 string binaryStr = format("{:b}", decimal);
16 // Result: "1010"
```

## 8.2 Coordinate Compression

Efficiently map large values to smaller ranges for data structures.

60: Coordinate Compression Template

```

1 template <typename T>
2 class Compress {
3     vector<T> vals;
4     unordered_map<T, int> idx;
5
6 public:
7     Compress(const vector<T>& input) {
8         vals = input;
9         sort(vals.begin(), vals.end());
10        vals.erase(unique(vals.begin(), vals.end()), vals.end());
11        for (int i = 0; i < vals.size(); i++)
12            idx[vals[i]] = i;
13    }
14
15    int operator[](const T& x) const { return idx.at(x); }
16    T orig(int i) const { return vals.at(i); }
17    int size() const { return vals.size(); }
18 };

```

61: Coordinate Compression Example

```

1 // Basic usage
2 vector<int> data = {1000000, 5, 10000, 6, 7, 1000};
3 Compress<int> comp(data);
4
5 // Convert original value to compressed index
6 for (int x : data) {
7     cout << x << " -> " << comp[x] << endl;
8 }
9 // Output: 1000000->5, 5->0, 10000->3, 6->1, 7->2, 1000->4
10
11 // Get original value from compressed index
12 for (int i = 0; i < comp.size(); i++) {
13     cout << i << " -> " << comp.orig(i) << endl;
14 }
15 // Output: 0->5, 1->6, 2->7, 3->1000, 4->10000, 5->1000000

```

### Coordinate Compression Notes

- **Time Complexity:**  $O(N \log N)$  for construction,  $O(1)$  for lookup
- **Space Complexity:**  $O(N)$  for sorted list and hashmap

- 
- **Applications:** Segment trees, large value ranges, sparse data
  - **Features:** Preserves relative ordering, bidirectional mapping

### 8.3 Performance Utilities

Tools for measuring and optimizing code performance.

#### 62: Measure Time Utility

```
1 #include <iostream>
2 #include <chrono>
3 #include <cstdint>
4 #include <iomanip>
5 using namespace std;
6
7 template<typename Func, typename... Args>
8 double measure(Func&& f, Args&&... args) {
9     auto start = chrono::high_resolution_clock::now();
10    forward<Func>(f)(forward<Args>(args)...);
11    auto end = chrono::high_resolution_clock::now();
12    chrono::duration<double, milli> elapsed = end - start;
13    return elapsed.count();
14 }
15
16 int main() {
17     cout << fixed << setprecision(4);
18
19     double t1 = measure(funcVoid);
20     cout << "funcVoid took " << t1 << " ms\n";
21
22     int64_t res = 0;
23     auto wrapper = [&](int n) { res = funcInt(n); };
24     double t2 = measure(wrapper, 1000000);
25     cout << "funcInt took " << t2 << " ms, sum = " << res << "\n";
26
27     return 0;
28 }
```

#### Measure Time Notes

- **Template Function:** Works with any callable and arguments
- **High Resolution:** Uses `high_resolution_clock` for precision
- **Millisecond Precision:** Returns time in milliseconds
- **Applications:** Performance analysis, algorithm comparison
- **Wrapper Usage:** Use lambda wrapper for functions with return values

## 8.4 Random Number Generation

Generate random numbers for testing and simulation.

63: Random Number Generator

```
1 #include <iostream>
2 #include <random>
3 #include <ctime>
4 using namespace std;
5
6 mt19937_64 ran(time(nullptr));
7
8 int r(int a, int b) {
9     return ran() % (abs(b - a) + 1) + min(a, b);
10 }
```

64: Random Number Generator Example Usage

```
1 // Generate 5 random numbers between 1 and 100
2 for (int i = 0; i < 5; ++i) {
3     cout << r(1, 100) << " ";
4 }
5 // Output: e.g. 42 17 89 3 76
```

### Number Generator Notes

- **High Quality:** Uses mt19937\_64 for 64-bit random numbers
- **Range Function:**  $r(a, b)$  returns random integer in  $[\min(a,b), \max(a,b)]$
- **Time Seeding:** Seeded with current time
- **Applications:** Test case generation, competitive programming
- **Note:** Not cryptographically secure

## 8.5 String Utilities

Common string manipulation and parsing utilities.

### 65: String Split Utility

```
1 template<typename T>
2 vector<T> split(const string& line, char delimiter = ' ') {
3     vector<T> result;
4     stringstream ss(line);
5     string token;
6
7     while (getline(ss, token, delimiter)) {
8         stringstream convert(token);
9         T value;
10        convert >> value;
11        if (!convert.fail()) {
12            result.push_back(value);
13        }
14    }
15
16    return result;
17 }
18
19 // Basic string split to vector<string>
20 vector<string> split(const string& line, char delimiter = ' ') {
21     vector<string> result;
22     stringstream ss(line);
23     string token;
24     while (getline(ss, token, delimiter)) {
25         result.push_back(token);
26     }
27     return result;
28 }
```

### 66: String Split Examples

```
1 // Split string to vector<int>
2 vector<int> ints = split<int>("10 20 30"); // [10, 20, 30]
3
4 // Split string to vector<double> with comma delimiter
5 vector<double> doubles = split<double>("3.14,2.71,1.41", ','); // [3.14,
6     2.71, 1.41]
7
8 // Split input line to vector<int>
9 string input; getline(cin, input);
10 vector<int> values = split<int>(input);
```

**String Utilities Notes**

- **Template Function:** Works with any numeric type
- **Flexible Delimiter:** Default space, can specify any character
- **Error Handling:** Skips invalid conversions gracefully
- **Applications:** Input parsing, data processing

## 8.6 Custom Comparators

Custom comparators for sets, maps, and priority queues in C++.

### 67: Custom Comparator Approaches

```
1 // Struct comparator (descending):
2 struct Desc { bool operator()(int a, int b) const { return a > b; } };
3 set<int, Desc> s;
4 map<int, int, Desc> m;
5 priority_queue<int, vector<int>, Desc> pq;
6
7 // Lambda comparator (descending):
8 auto cmp = [](int a, int b) { return a > b; };
9 set<int, decltype(cmp)> s2(cmp);
10 map<int, int, decltype(cmp)> m2(cmp);
11 priority_queue<int, vector<int>, decltype(cmp)> pq2(cmp);
12
13 // Priority queues:
14 priority_queue<int> maxHeap; // max-heap (default)
15 priority_queue<int, vector<int>, greater<int>> minHeap; // min-heap
```

### Custom Comparators Notes

- **Struct Approach:** No need to pass comparator instance to constructor
- **Lambda Approach:** Must pass comparator instance to constructor
- **decltype:** Use to deduce lambda function type
- **Priority Queue Logic:** Comparator logic is reversed compared to set/map
- **Applications:** Reverse ordering, custom object sorting, specialized sorting
- **Important:** For priority\_queue, comparator returns true if first argument should come after second

## 9 Searching Algorithms

### 9.1 Binary Search

68: Binary Search Implementation

```
1 // Standard binary search
2 int binarySearch(vector<int>& arr, int target) {
3     int low = 0, high = arr.size() - 1;
4     while (low <= high) {
5         int mid = (low + high) / 2;
6         if (arr[mid] == target) return mid;
7         else if (arr[mid] < target) low = mid + 1;
8         else high = mid - 1;
9     }
10    return -1;
11 }
12
13 // Using STL binary_search
14 bool found = binary_search(arr.begin(), arr.end(), target);
```

### 9.2 Lower Bound / Upper Bound

69: Lower Bound Implementation

```
1 // Manual lower bound
2 int lowerBound(vector<int>& arr, int target) {
3     int low = 0, high = arr.size() - 1, index = -1;
4     while (low <= high) {
5         int mid = (low + high) / 2;
6         if (arr[mid] >= target) {
7             index = mid;
8             high = mid - 1;
9         } else {
10            low = mid + 1;
11        }
12    }
13    return index;
14 }
15
16 // Using STL lower_bound
17 int index = lower_bound(arr.begin(), arr.end(), target) - arr.begin();
```

## 70: Upper Bound Implementation

```
1 // Manual upper bound
2 int upperBound(vector<int>& arr, int target) {
3     int low = 0, high = arr.size() - 1, index = -1;
4     while (low <= high) {
5         int mid = (low + high) / 2;
6         if (arr[mid] > target) {
7             index = mid;
8             high = mid - 1;
9         } else {
10            low = mid + 1;
11        }
12    }
13    return index;
14 }
15
16 // Using STL upper_bound
17 int index = upper_bound(arr.begin(), arr.end(), target) - arr.begin();
```

### 9.3 Binary Search on Answer

```
1 // Binary search on answer when we need to find minimum/maximum
2 // that satisfies some condition
3 long long binarySearchOnAnswer(long long left, long long right, function<
4     bool(long long)> check) {
5     long long ans = right;
6     while (left <= right) {
7         long long mid = left + (right - left) / 2;
8         if (check(mid)) {
9             ans = mid;
10            right = mid - 1; // For minimum
11            // left = mid + 1; // For maximum
12        } else {
13            left = mid + 1; // For minimum
14            // right = mid - 1; // For maximum
15        }
16    }
17    return ans;
18 }
19 // Example: Find minimum time to complete a task
20 bool canComplete(vector<int>& tasks, long long time) {
21     long long total = 0;
22     for (int task : tasks) {
23         total += (time + task - 1) / task; // Ceiling division
24     }
25     return total <= time;
26 }
```

## 9.4 Ternary Search

```
1 // Integer ternary search for unimodal function
2 int ternarySearchInt(int left, int right, function<int(int)> f) {
3     while (right - left > 3) {
4         int mid1 = left + (right - left) / 3;
5         int mid2 = right - (right - left) / 3;
6
7         if (f(mid1) < f(mid2)) {
8             left = mid1;
9         } else {
10             right = mid2;
11         }
12     }
13
14     // Check remaining points
15     int best = left;
16     for (int i = left; i <= right; i++) {
17         if (f(i) < f(best)) best = i;
18     }
19
20     return best;
21 }
22
23 // Floating point ternary search
24 double ternarySearchDouble(double left, double right, function<double(double)> f, double eps = 1e-9) {
25     while (right - left > eps) {
26         double mid1 = left + (right - left) / 3;
27         double mid2 = right - (right - left) / 3;
28
29         if (f(mid1) < f(mid2)) {
30             left = mid1;
31         } else {
32             right = mid2;
33         }
34     }
35
36     return left;
37 }
```

## 10 Geometry (CP Basics)

### 10.1 Points & Vectors

71: Point and Vector Structure

```
1 #include <bits/stdc++.h>
2 using namespace std;
3
4 const double EPS = 1e-9;
5 const double PI = acos(-1.0);
6
7 struct Point {
8     double x, y;
9     Point(double x = 0, double y = 0) : x(x), y(y) {}
10
11     Point operator+(Point p) { return Point(x + p.x, y + p.y); }
12     Point operator-(Point p) { return Point(x - p.x, y - p.y); }
13     Point operator*(double t) { return Point(x * t, y * t); }
14
15     double dot(Point p) { return x * p.x + y * p.y; }
16     double cross(Point p) { return x * p.y - y * p.x; }
17     double norm() { return sqrt(x * x + y * y); }
18     Point rotate(double a) {
19         return Point(x*cos(a) - y*sin(a), x*sin(a) + y*cos(a));
20     }
21 };
22
23 double dist(Point a, Point b) { return (a - b).norm(); }
```

## 10.2 Lines & Segments

### 72: Line and Segment Operations

```
1 // Distance point to line
2 double distPointLine(Point p, Point a, Point b) {
3     return abs((b - a).cross(p - a)) / (b - a).norm();
4 }
5
6 // Distance point to segment
7 double distPointSeg(Point p, Point a, Point b) {
8     if ((b - a).dot(p - a) < 0) return (p - a).norm();
9     if ((a - b).dot(p - b) < 0) return (p - b).norm();
10    return distPointLine(p, a, b);
11 }
12
13 // Line intersection
14 bool lineIntersect(Point a1, Point b1, Point a2, Point b2, Point& res) {
15     Point d1 = b1 - a1, d2 = b2 - a2;
16     double cross = d1.cross(d2);
17     if (abs(cross) < EPS) return false;
18     double t = (a2 - a1).cross(d2) / cross;
19     res = a1 + d1 * t;
20     return true;
21 }
22
23 // Segment intersection
24 bool segIntersect(Point a1, Point b1, Point a2, Point b2) {
25     Point d1 = b1 - a1, d2 = b2 - a2;
26     double cross = d1.cross(d2);
27     if (abs(cross) < EPS) return false;
28     double t1 = (a2 - a1).cross(d2) / cross;
29     double t2 = (a2 - a1).cross(d1) / cross;
30     return t1 >= 0 && t1 <= 1 && t2 >= 0 && t2 <= 1;
31 }
```

## 10.3 Polygons & Areas

### 73: Polygon Area Calculations

```
1 // Polygon area (signed)
2 double polyArea(vector<Point>& poly) {
3     double area = 0;
4     int n = poly.size();
5     for (int i = 0; i < n; i++)
6         area += poly[i].cross(poly[(i + 1) % n]);
7     return area / 2.0;
8 }
9
10 // Alternative polygon area (triangulation from first vertex)
11 double polyAreaAlt(vector<Point>& poly) {
12     double area = 0;
13     for (int i = 1; i < poly.size() - 1; i++)
